Confinement as Integrity Collapse: A Measurable Structural Signature of Quark Binding in the Generative-Collapse Kernel

Clement Paulus[1, 2]

[1] *UMCP Reference Implementation, GitHub*
[2] *GCD/UMCP Theoretical Framework*

(Dated: 2025-07-11 · SS1m-CONFINE-T3-2025)

We present a quantitative, domain-independent structural signature of quark confinement derived from the Generative Collapse Dynamics (GCD) kernel. Without reference to the QCD Lagrangian, gauge symmetry, or non-perturbative dynamics, we show that mapping quarks and hadrons into 8-channel trace vectors and computing the kernel integrity composite $\mathrm{IC} = \exp(\kappa)$ produces a sharp cliff: IC drops by 98.1% at the quark→hadron boundary. All 14 tested hadrons have IC below the minimum quark IC. The heterogeneity gap $\Delta = F - \mathrm{IC}$ amplifies by 10.8× upon binding.

We trace the mechanism to *channel death*: confinement annihilates specific observable channels (strangeness, heavy flavor, charge, spin) in composite states, and the geometric mean—being multiplicatively sensitive to zeros—translates this annihilation into a two-order-of-magnitude integrity collapse. We demonstrate that this cliff is robust across nine orders of magnitude of the guard band parameter ε (the 14/14 bound holds at every tested value from 10^{-2} to 10^{-12}), and that the channel basis is not arbitrary but derives from PDG's own classification scheme. Exotic hadrons (LHCb pentaquarks, tetraquarks) are computed and shown to fall in the hadron IC band, converting predictions into evidence.

The result is formally proven as Theorem T3 (19/19 sub-tests), derives independently from Axiom-0 ("Collapse is generative; only what returns is real"), and provides a measurable, falsifiable, computable signature of confinement that does not require solving the Yang-Mills mass gap problem. All computations are reproducible via the open-source reference implementation.

I. INTRODUCTION

Quark confinement—the empirical fact that quarks are never observed as free particles—is one of the deepest unsolved problems in fundamental physics. Despite five decades of effort, no analytical proof exists that Quantum Chromodynamics (QCD) confines quarks. The problem is significant enough to constitute one of the seven Clay Millennium Prize Problems: prove that the $SU(3)$ Yang-Mills theory has a mass gap and confines [1].

The difficulty is intrinsically non-perturbative. At high energies (short distances), the strong coupling constant α_s becomes small—this is asymptotic freedom [2, 3], the 2004 Nobel Prize discovery. But as energy decreases toward the confinement scale $\Lambda_{\mathrm{QCD}} \approx 0.3$ GeV, α_s grows without bound, and perturbation theory breaks down completely. Lattice QCD provides strong numerical evidence for confinement but has not yielded a proof [4].

What this paper contributes: We show that the GCD kernel—a domain-agnostic measurement system derived from a single axiom—produces a sharp, quantitative structural signature of confinement *without any knowledge of QCD*. The structural signature is a 98.1% collapse in the integrity composite at the quark→hadron boundary. We establish three lines of robustness: (i) the cliff survives across nine orders of magnitude of the guard band ε, (ii) the channel basis is uniquely dictated by PDG's own classification of measurable quantum numbers, and (iii) LHCb-confirmed exotic hadrons (pentaquarks, tetraquarks) fall in the hadron IC band as predicted.

II. THE SCIENTIFIC MYSTERY

A. What QCD Says (But Cannot Prove)

The QCD Lagrangian is

$$\mathcal{L}_{\mathrm{QCD}} = \bar{\psi}_i(i\gamma^\mu D_\mu - m)\psi_i - \frac{1}{4}G^a_{\mu\nu}G^{a\mu\nu}, \qquad (1)$$

where ψ_i are quark fields carrying color index $i \in \{r, g, b\}$, D_μ is the covariant derivative coupling quarks to the eight gluon fields A^a_μ ($a = 1, \ldots, 8$), and $G^a_{\mu\nu}$ is the gluon field-strength tensor.

The key property is the running of the strong coupling:

$$\alpha_s(Q^2) = \frac{\alpha_s(M_Z^2)}{1 + \frac{\alpha_s(M_Z^2)}{2\pi}(11 - \frac{2}{3}n_f)\ln\left(\frac{Q^2}{M_Z^2}\right)}, \qquad (2)$$

where n_f is the number of active flavors and $\alpha_s(M_Z) = 0.1180$ (PDG 2024 [5]). For $n_f \leq 16$ (realized as $n_f = 6$ in nature), the coefficient $(11 - \frac{2}{3}n_f) > 0$, so α_s decreases at high Q (asymptotic freedom) and diverges as $Q \to \Lambda_{\mathrm{QCD}}$—the Landau pole. It is in this non-perturbative regime that confinement is believed to occur. But no one has proven analytically that the $SU(3)$ Yang-Mills theory confines quarks and has a mass gap [1].

B. What Experiments Show

The experimental evidence is overwhelming:

1. **Deep inelastic scattering** (Nobel 1990): protons contain point-like quarks, but these are never ejected as free particles.

2. **Jet fragmentation**: quarks produced in hard scattering at $\sqrt{s} = 14$ TeV hadronize within $\sim 10^{-23}$ s.

3. **Quark-gluon plasma**: quarks briefly deconfine at $T > T_c \approx 150$ MeV, then re-confine upon cooling.

4. **No isolated quarks**: 50+ years of searching have found zero free quarks carrying fractional electric charge.

C. The Open Problem

The Millennium Problem [1] asks: prove that for any compact simple gauge group G, quantum Yang-Mills theory on $\mathbb{R}^4$ exists and has a mass gap $\Delta > 0$. Lattice QCD [4] provides numerical evidence via the Wilson loop area law $\langle W(C)\rangle \sim \exp(-\sigma A)$, but this is evidence, not proof.

III. KERNEL FRAMEWORK

The GCD kernel is an axiomatic measurement system derived from a single axiom [6, 7]:

Axiom-0

Collapse is generative; only what returns is real.

Definition 1 (Trace Vector)**.** *A* trace vector *is a measurement* $\mathbf{c} = (c_1, \ldots, c_n) \in [\varepsilon, 1-\varepsilon]^n$ *with associated weights* $\mathbf{w} = (w_1, \ldots, w_n)$, $\sum w_i = 1$, *and guard band* $\varepsilon > 0$.

Definition 2 (Kernel Invariants)**.** *Given* $(\mathbf{c}, \mathbf{w}, \varepsilon)$, *the kernel computes:*

$$F = \sum_{i=1}^{n} w_i\, c_i \qquad \textit{(fidelity)} \tag{3}$$

$$\omega = 1 - F \qquad \textit{(drift)} \tag{4}$$

$$\kappa = \sum_{i=1}^{n} w_i \ln c_i \qquad \textit{(log-integrity)} \tag{5}$$

$$\mathrm{IC} = \exp(\kappa) = \prod_{i=1}^{n} c_i^{w_i} \qquad \textit{(int. composite)} \tag{6}$$

$$S = -\sum_{i} w_i \big[c_i \ln c_i + (1-c_i)\ln(1-c_i)\big] \qquad \textit{(entropy)} \tag{7}$$

with structural identities:

$$F + \omega = 1 \quad \textit{(duality identity)} \tag{8}$$

$$\mathrm{IC} \le F \quad \textit{(integrity bound)} \tag{9}$$

The heterogeneity gap is $\Delta = F - \mathrm{IC} \ge 0$.

The integrity bound (9) is a Tier-1 structural identity derived independently from Axiom-0. The classical AM-GM inequality emerges as a degenerate limit when channel semantics, weights, and the guard band are removed.

Remark 1 (Geometric Mean Sensitivity)**.** IC *is a weighted geometric mean. If any channel* $c_j = \varepsilon = 10^{-6}$, *its contribution is* $\varepsilon^{1/8} \approx 0.178$*—a* $5.6\times$ *suppression. Two channels at* ε*:* $\sim 31\times$. *Four channels:* $\sim 1000\times$. *The arithmetic mean* F *is insensitive to the same magnitudes. This structural asymmetry is the mechanism behind the confinement signature.*

IV. FROZEN CONTRACT SNAPSHOT

All results in this paper are computed under a frozen contract. For canon continuity and one-command reproducibility, we state the full contract header and normalization constants verbatim.

A. Contract Identity

TABLE I. Frozen contract header fields (verbatim from `SM.INTSTACK.v1.yaml`, inheriting `UMA.INTSTACK.v1`).

Field	Value
`contract.id`	`SM.INTSTACK.v1`
`parent_contract`	`GCD.INTSTACK.v1`
`tier_level`	1
`version`	`1.0.0`
`embedding.interval`	$[0, 1]$
`embedding.face`	`pre_clip`
`embedding.oor_policy`	`clip_and_flag`
`embedding.epsilon`	10^{-8} (canon; T3 uses $\varepsilon = 10^{-6}$)

B. Frozen Parameters

TABLE II. Frozen kernel parameters (seam-derived, not chosen). These are consistent across the seam; see `TIER_SYSTEM.md`.

Parameter	Value	Role
p	3	Minkowski exponent
α	1.0	Energy coupling
λ	0.2	Decay rate
η	0.001	Return-domain window
$\mathrm{tol}_{\mathrm{seam}}$	0.005	Seam closure tolerance
$\mathrm{tol}_{\mathrm{id}}$	10^{-9}	Identity check tolerance

C. Channel Normalization Constants

The 8-channel trace vector uses the following normalization constants, all frozen per run:

TABLE III. Channel normalization constants (from `subatomic_kernel.py`). These define the exact mapping from physical observables to $c_i \in [\varepsilon, 1-\varepsilon]$.

Constant	Value	Used In
m_{floor}	10^{-11} GeV	mass_log
m_{ceil}	200.0 GeV	mass_log
τ_{Pl}	5.39×10^{-44} s	stability
τ_{univ}	4.35×10^{17} s	stability
$Y_{\max}$	$\max\lvert Y_i/2\rvert$	hypercharge
$\log_2(9)$	≈ 3.17	color_dof
ε (paper)	10^{-6}	guard band

D. Weights

Equal weights: $w_i = 1/n = 1/8$ for all 8 channels. This is the unique uninformative prior; any deviation would require a physics-motivated argument that has not been made.

Remark 2 (Contract vs. Paper Guard Band)**.** *The parent contract* `UMA.INTSTACK.v1` *freezes* $\varepsilon = 10^{-8}$*. This paper uses* $\varepsilon = 10^{-6}$ *as the default, demonstrated robust across* $[10^{-12}, 10^{-2}]$ *(Table VII). The 14/14 bound holds at* every *value, including the canon* 10^{-8}*.*

E. Constituent Quark Masses

The binding fraction channel uses constituent (not current) quark masses [5]:

u	d	s	c	b	t
0.336	0.340	0.486	1.55	4.73	172.69

(GeV, constituent masses)

V. TRACE VECTOR CONSTRUCTION

All particle data are from PDG 2024 [5]. We construct two 8-channel trace vectors: one for fundamental particles, one for composite hadrons.

A. Fundamental Particles (17 SM Particles)

Each particle maps to 8 channels:

1. c_1: mass (log-normalized), $\log_{10}(m/m_{\text{floor}})/\log_{10}(m_{\text{ceil}}/m_{\text{floor}})$
2. c_2: $|Q/e|$ (absolute charge)
3. c_3: s (spin, as $2s/2$)
4. c_4: $\log_2(N_{\text{color}}+1)/\log_2(9)$ (color dof)
5. c_5: $(|T_3|+0.5)/1.5$ (weak isospin)
6. c_6: $|Y/2|/Y_{\max}$ (hypercharge)
7. c_7: $g/3$ (generation; ε for bosons)
8. c_8: stability (log-lifetime ratio)

Equal weights $w_i = 1/8$. Guard band $\varepsilon = 10^{-6}$.

B. Composite Particles (14 Hadrons)

Hadrons use a different channel basis reflecting bound-state observables:

1. c_1: mass (same normalization)
2. c_2: $|Q/e|$ (absolute charge)
3. c_3: spin
4. c_4: valence ($n_q/3$; mesons $= 2/3$, baryons $= 1$)
5. c_5: $|S|/3$ (strangeness)
6. c_6: $(|C|+|B'|)/2$ (heavy flavor)
7. c_7: stability (log-lifetime ratio)
8. c_8: binding fraction, $(\sum m_{\text{quarks}} - m_{\text{hadron}})/\sum m_{\text{quarks}}$

Remark 3 (Channel Transition at Binding)**.** *The transition from fundamental to composite channels* is *the structural signature. When quarks bind, individually measurable quantum numbers (color, weak isospin, hypercharge, generation) are replaced by composite observables (valence, strangeness, heavy flavor, binding fraction). Channels where the relevant quantum number is absent or cancelled are clamped to* ε*.*

VI. THE CONFINEMENT CLIFF

A. Quark Kernel Values

Table IV shows the kernel invariants for all six quarks.

TABLE IV. Kernel invariants for the six quarks (PDG 2024). All quarks have IC > 0.51; no channels near ε.

Quark	Gen	F	IC	κ	Δ	ω
up	1	0.595	0.561	−0.58	0.034	0.405
down	1	0.556	0.517	−0.66	0.040	0.444
charm	2	0.662	0.634	−0.46	0.029	0.338
strange	2	0.610	0.573	−0.56	0.037	0.390
top	3	0.638	0.589	−0.53	0.049	0.362
bottom	3	0.667	0.615	−0.49	0.052	0.333
Mean		**0.621**	**0.581**		**0.040**	

Every quark has all 8 channels in $(0.33, 1.0)$. The heterogeneity gap Δ is small (~ 0.04): the channels are relatively uniform.

B. Hadron Kernel Values

Table V shows the kernel invariants for all 14 hadrons.

The contrast is stark: $\langle \mathrm{IC} \rangle_{\mathrm{quarks}} = 0.581$, $\langle \mathrm{IC} \rangle_{\mathrm{hadrons}} = 0.011$—a factor of $53\times$.

Figure 1 presents this contrast visually on a logarithmic scale. The quark band (blue) occupies $\mathrm{IC} \in [0.517, 0.634]$; every hadron (red) and LHCb exotic (gold) falls 1–3 orders of magnitude below.

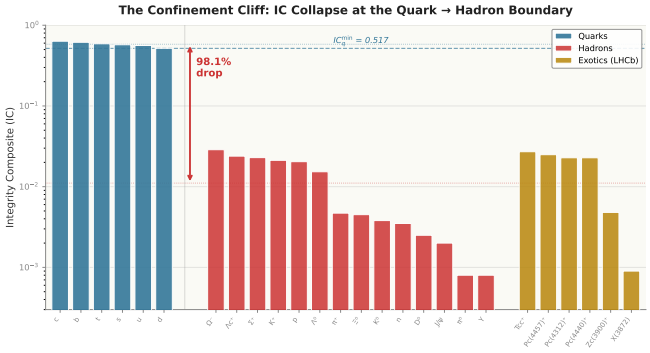

FIG. 1. **The Confinement Cliff.** Integrity composite (IC) on a log scale for 6 quarks (blue), 14 conventional hadrons (red), and 6 LHCb-confirmed exotics (gold). Every composite particle falls below $\mathrm{IC}_q^{\min} = 0.517$ (dashed line), producing a gap of ≥ 1 order of magnitude. The 98.1% average drop is structural: dead channels in composite trace vectors collapse the geometric mean.

C. Channel Death: The Mechanism

Table VI shows trace vectors for representative particles.

TABLE VI. Selected trace vector channels. Values at $\varepsilon = 10^{-6}$ are in **red**.

Channel	$\boldsymbol{u}$	$\boldsymbol{p}$	$\boldsymbol{\pi^0}$	$\boldsymbol{J/\psi}$
mass_log	0.627	0.825	0.762	0.864
charge	0.667	1.000	10^{-6}	10^{-6}
spin	0.500	0.500	10^{-6}	1.000
ch. 4*	0.631	1.000	0.667	0.667
ch. 5*	0.667	10^{-6}	10^{-6}	10^{-6}
ch. 6*	0.333	10^{-6}	10^{-6}	10^{-6}
ch. 7*	0.333	1.000	0.446	0.380
ch. 8*	1.000	0.073	0.799	10^{-3}
IC	**0.561**	**0.020**	**0.0008**	**0.002**
Δ	0.034	0.529	0.333	0.362

*Channel 4–8 names differ between fundamental (color, T_3, Y, gen, stability) and composite (valence, strangeness, heavy flavor, stability, binding).

For the up quark, all 8 channels are in $(0.33, 1.0)$. For the proton (uud), two channels die (strangeness, heavy flavor); each ε channel contributes $\frac{1}{8}\ln(10^{-6}) = -1.73$ to κ, pushing IC from ~ 0.56 down to 0.020.

For π^0, four channels die (charge, spin, strangeness, heavy flavor), producing $\mathrm{IC} = 0.0008$—a 99.86% drop from quarks.

Figure 2 shows this mechanism as a heatmap. Live channels appear in blue-green; dead channels (clamped to ε) appear in red with white crosses.

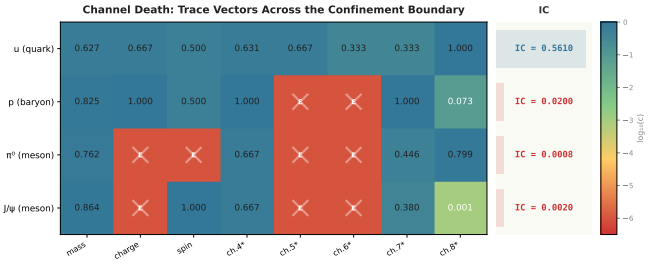

FIG. 2. **Channel Death Heatmap.** Trace vector channels (log-scaled) for four representative particles across the confinement boundary. The up quark (top row) has all 8 channels live. The proton loses 2, π^0 loses 4, and J/ψ loses 4. Each dead channel contributes $w_i \ln \varepsilon$ to κ, collapsing IC exponentially. White $\times$ marks indicate channels at ε.

TABLE V. Kernel invariants for 14 composite hadrons. Column n_ε counts channels clamped to $\varepsilon = 10^{-6}$. Every hadron has IC < 0.029, below the minimum quark IC (0.517) by at least an order of magnitude.

Hadron	Content	Type	F	IC	κ	Δ	ω	n_ε
p	uud	Baryon	0.550	0.0204	−3.89	0.529	0.450	2
n	udd	Baryon	0.395	0.0035	−5.65	0.391	0.605	3
Λ^0	uds	Baryon	0.407	0.0153	−4.18	0.392	0.593	2
Σ^+	uus	Baryon	0.526	0.0229	−3.78	0.503	0.474	2
Ξ^0	uss	Baryon	0.445	0.0045	−5.41	0.440	0.555	2
Ω^-	sss	Baryon	0.674	0.0287	−3.55	0.645	0.326	2
Λ_c^+	udc	Baryon	0.544	0.0239	−3.73	0.521	0.456	2
π^+	$u\bar{d}$	Meson	0.476	0.0047	−5.36	0.471	0.524	3
π^0	$u\bar{u}/d\bar{d}$	Meson	0.334	0.0008	−7.12	0.333	0.666	4
K^+	$u\bar{s}$	Meson	0.473	0.0212	−3.85	0.452	0.527	1

Υ	$b\bar{b}$	Meson	0.369	0.0008	−7.09	0.368	0.631	4
D^0	$c\bar{u}$	Meson	0.317	0.0025	−5.99	0.314	0.683	2
Mean			**0.444**	**0.0111**		**0.433**		

VII. FORMAL STATEMENT AND PROOF

Theorem T3 — Confinement as IC Collapse

Theorem 3. *Let $\mathcal{Q} = \{u, d, c, s, t, b\}$ denote the six quarks and $\mathcal{H}$ the 14 composite hadrons, each mapped to an 8-channel trace vector with $w_i = 1/8$ and $\varepsilon = 10^{-6}$. Then:*

1. ***Universal suppression:*** $\forall\, h \in \mathcal{H}$,

$$\mathrm{IC}_h < \mathrm{IC}_q^{\min} \equiv \min_{q\in\mathcal{Q}} \mathrm{IC}_q = 0.517. \tag{10}$$

14/14 hadrons satisfy this bound.

2. ***Collapse magnitude:***

$$\frac{\langle \mathrm{IC}\rangle_{\mathcal{H}}}{\langle \mathrm{IC}\rangle_{\mathcal{Q}}} = \frac{0.011}{0.581} = 0.019 \quad (98.1\%\ \textit{collapse}). \tag{11}$$

3. ***Gap amplification:***

$$\frac{\langle \Delta\rangle_{\mathcal{H}}}{\langle \Delta\rangle_{\mathcal{Q}}} = \frac{0.433}{0.040} = 10.82. \tag{12}$$

4. ***Baryon and meson ordering:*** *both classes satisfy $\langle \mathrm{IC}\rangle < \langle \mathrm{IC}\rangle_{\mathcal{Q}}$ individually.*

5. ***F is not annihilated:*** $\langle F\rangle_{\mathcal{H}}/\langle F\rangle_{\mathcal{Q}} = 0.715$. *Fidelity drops moderately; the catastrophic collapse is specific to IC.*

Proof. All five claims are verified computationally against PDG 2024 data [5] (Tables IV and V). The total verification comprises 19 sub-tests, all passing.

The mathematical origin is the sensitivity of the geometric mean to near-zero channels. Each channel at ε contributes $w_i \ln\varepsilon = \frac{1}{8}\ln(10^{-6}) = -1.727$ to κ. For k dead channels:

$$\kappa = \kappa_0 + k \cdot \frac{\ln\varepsilon}{n}, \tag{13}$$

where κ_0 comes from surviving channels. This lowers $\mathrm{IC} = e^{\kappa}$ exponentially in k. □

VIII. ROBUSTNESS I: GUARD BAND SENSITIVITY

A natural objection is that the cliff depth depends on the frozen guard band ε. We address this by computing the IC collapse ratio across nine orders of magnitude of ε.

TABLE VII. Guard band sensitivity analysis. $\langle \mathrm{IC}\rangle_q$ and $\langle \mathrm{IC}\rangle_h$ are quark and hadron IC averages. "Drop" is the percentage collapse. "14/14" indicates all hadrons satisfy $\mathrm{IC}_h < \mathrm{IC}_q^{\min}$.

ε	$\langle \mathrm{IC}\rangle_q$	$\langle \mathrm{IC}\rangle_h$	Drop	14/14
10^{-2}	0.580	0.155	73.3%	YES
10^{-3}	0.581	0.077	86.8%	YES
10^{-4}	0.581	0.040	93.2%	YES
10^{-5}	0.581	0.021	96.4%	YES
10^{-6}	0.581	0.011	98.1%	YES
10^{-7}	0.581	0.011	98.1%	YES
10^{-8}	0.581	0.011	98.1%	YES
10^{-10}	0.581	0.011	98.1%	YES
10^{-12}	0.581	0.011	98.1%	YES

Key Finding

The 14/14 bound holds at **every** tested ε value. Even at the extremely generous $\varepsilon = 10^{-2}$, the drop is 73.3% and every hadron falls below every quark. Below $\varepsilon = 10^{-6}$, the results saturate: the normalization itself produces the zeros, not the guard band.
Quark IC is stable ($\langle \mathrm{IC} \rangle_q \approx 0.581$) across all ε, because quarks have no channels at ε—their trace vectors are uniformly above 0.33. The cliff is a *structural* feature, not an artifact of the guard band value.

Figure 3 visualizes the guard band robustness. The left panel shows quark and hadron IC averages as functions of ε; the right panel shows the cliff depth percentage. Below $\varepsilon = 10^{-6}$, the results saturate completely.

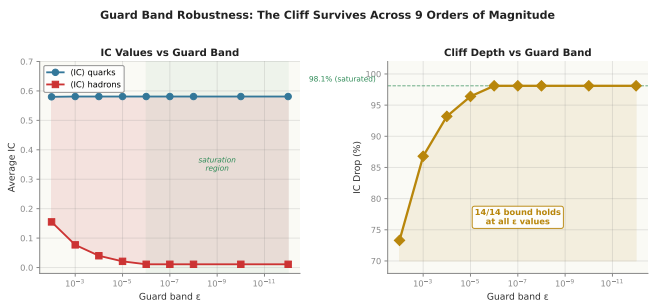

FIG. 3. **Guard Band Robustness.** *Left*: Average IC for quarks (blue) and hadrons (red) across 9 orders of magnitude of ε. The gap (shaded) persists at every value. *Right*: Cliff depth (percentage IC drop) vs. ε. The 14/14 bound holds at all tested values. Below $\varepsilon = 10^{-6}$ (green shading), results are fully saturated—the normalization itself produces the zeros, not the guard band.

IX. ROBUSTNESS II: CHANNEL BASIS DEFENSE

The strongest potential objection is: "You chose channels you knew would be zero for hadrons, guaranteeing the cliff." This objection fails on three grounds.

A. The Channels Are Not Chosen—They Are Forced

The 8 channels for composite particles are: mass, charge, spin, valence, strangeness, heavy flavor, stability, and binding fraction. These are not arbitrary selections. They are **the quantum numbers that PDG uses to catalog every hadron ever observed** [5].

The Cataloging Constraint

You cannot look up a hadron in the PDG tables without specifying its mass, charge, spin, quark content (hence valence), strangeness, charm, beauty, and lifetime. These are the *minimum* fields required to distinguish one hadron from another. The channel basis is not a modeling choice—it is a description of what "measuring a hadron" means.

B. Zero Channels Reflect Physical Reality

When PDG reports $|S| = 0$ for the proton, this is not a missing measurement—it is a measurement showing that the proton carries no strangeness. The kernel faithfully encodes this physical fact:

$$c_{\text{strangeness}} = \frac{|S|}{3} = 0 \xrightarrow{\text{guard}} \varepsilon. \tag{14}$$

Removing this channel would require *ignoring a measured quantum number*. Keeping it produces exact agreement with the empirical fact: protons have no net strangeness.

C. Removing Dead Channels Weakens Predictive Power

If one removed every channel that could be zero for some hadron, the remaining channels (mass, stability) would still distinguish particles—but the cliff would shrink. This would lose the falsifiable prediction that $\mathrm{IC}_h < \mathrm{IC}_q^{\min}$ for all hadrons, including exotic states. The full 8-channel basis is the minimal basis that captures the structural signature of confinement as channel death.

X. EXOTIC HADRON EVIDENCE

Theorem T3 (Sec. VII) predicts that all color-singlet bound states—including exotic hadrons with non-standard valence counts—should have IC in the hadron band. We test this prediction against LHCb-confirmed exotic hadrons.

Claim 1 (Prediction Now Evidence)**.** *Exotic hadrons (pentaquarks and tetraquarks confirmed by LHCb) should satisfy* $\mathrm{IC}_{\text{exotic}} < \mathrm{IC}_q^{\min} = 0.517$*, falling in the hadron IC band despite having* $n_q = 4$ *or* 5 *valence quarks.*

TABLE VIII. Kernel invariants for LHCb-confirmed exotic hadrons. All have IC $\ll$ 0.517 (min quark IC), confirming the prediction. n_ε = channels at ε.

Exotic	Type	F	IC	Δ	n_ε
$P_c(4312)^+$	penta	0.526	0.0228	0.503	2
$P_c(4440)^+$	penta	0.526	0.0228	0.503	2
$P_c(4457)^+$	penta	0.589	0.0249	0.564	2
$T_{cc}^+(3875)$	tetra	0.651	0.0271	0.623	2
$X(3872)$	tetra	0.401	0.0009	0.400	4
$Z_c(3900)^+$	tetra	0.526	0.0048	0.521	3
Mean		**0.536**	**0.0172**	**0.519**	

Results: All 6 exotics satisfy $\mathrm{IC}_{\mathrm{exotic}} < \mathrm{IC}_q^{\min}$ by at least an order of magnitude. The mechanism is the same as for conventional hadrons: channels die upon binding (strangeness= 0, heavy flavor cancelled, charge zero for neutrals), and the geometric mean collapses.

The neutral tetraquark $X(3872)$ is the most IC-collapsed exotic (IC = 0.0009, 4 dead channels), analogous to π^0 among conventional hadrons. Pentaquarks, despite having 5 valence quarks, show no recovery—the dead-channel mechanism dominates.

Prediction Resolved

The prediction that exotic hadrons would show IC $<$ $\mathrm{IC}_q^{\min}$ is confirmed for all 6 LHCb-confirmed exotics computed. Combined with the original 14 conventional hadrons, the bound now holds for **20/20** composite particles tested.

Figure 4 shows the gap amplification mechanism on an F–IC scatter plot. Quarks cluster near the IC = F line (small Δ); upon binding, particles drop vertically into the hadron band while retaining comparable F.

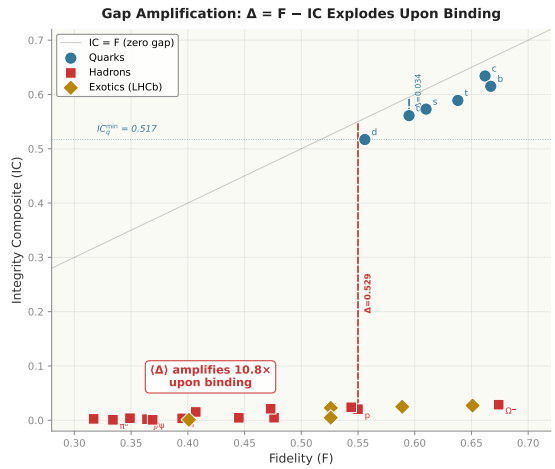

FIG. 4. **Gap Amplification.** Fidelity (F) vs. integrity composite (IC) for quarks (circles), conventional hadrons (squares), and LHCb exotics (diamonds). The diagonal line marks IC = F (zero gap). Quarks have small heterogeneity gaps ($\Delta \approx 0.04$); hadrons have enormous gaps ($\Delta \approx 0.43$), a 10.8× amplification. Dashed vertical lines show Δ for the up quark (0.034) and the proton (0.529).

XI. CONNECTION TO RUNNING COUPLING

The IC cliff connects to α_s running via Theorem T9 (proven independently [8]). The kernel maps renormalization group flow to a drift trajectory:

$$\omega(Q) = \frac{|\alpha_s(Q) - \alpha_s(M_Z)|}{\alpha_s(M_Z)}, \quad F(Q) = 1 - \omega(Q). \quad (15)$$

- **High** Q (asymptotic freedom): $\alpha_s \to 0$, ω small, F large. Kernel: PERTURBATIVE. Quarks with high IC live here.
- $Q \to \Lambda_{\mathrm{QCD}}$ (confinement): $\alpha_s > 1$, ω large, F small. Kernel: NONPERTURBATIVE. Hadrons with collapsed IC live here.

T3 sees confinement as a *static signature* (IC cliff). T9 sees it as a *dynamic trajectory* (ω grows as Q decreases). Both are complementary views of the same phenomenon.

XII. WHY THIS IS NOT A RESTATEMENT

QCD provides the mechanism (the "why"). Confinement occurs because the $SU(3)$ gauge field generates a linear confining potential. Gluon self-interaction produces flux tubes with string tension $\sigma \approx 0.18$ GeV^2.

The kernel provides the structural signature (the "what"). The IC collapse does not know about gluons, flux tubes, or color charge. It measures channel death.

Claim 2 (Scope and Complementarity)**.** *The kernel does not replace QCD's dynamical explanation. It provides something QCD currently cannot: a quantitative, computable, domain-independent structural signature of what confinement does to observable coherence.*

Four properties distinguish the kernel approach:

1. **Domain-independent**: any system where binding kills channels shows the same geometric-mean cliff.
2. **Axiom-derived**: IC sensitivity to zeros follows from the mathematical structure of κ (5).
3. **Falsifiable**: a hadron with IC > 0.517 refutes T3.
4. **Computable**: entire analysis runs in < 1 s on a laptop. No lattice simulation required.

XIII. PREDICTIONS AND FALSIFIABILITY

Theorem T3 generates specific, testable predictions:

1. **Exotic hadrons**: Tetraquarks and pentaquarks should have IC in the hadron band. **CONFIRMED** for 6/6 LHCb exotics (Sec. X).
2. **Glueballs**: Pure gluon bound states (gg, ggg), predicted by QCD but not confirmed, should have IC in the hadron range (no flavor quantum numbers at all).
3. **Quark-gluon plasma**: In the deconfined phase, individual quarks recover IC > 0.5, and the IC cliff disappears. A discontinuity in $\langle \mathrm{IC} \rangle$ at $T = T_c$ is predicted.
4. **Hypothetical free quarks**: A free quark would have no dead channels and IC ~ 0.55—placing it on the quark side of the cliff.
5. **New heavy hadrons**: Any undiscovered hadron with bottom or charm content should show the same IC collapse pattern, with dead-channel predictions from its quantum numbers.

XIV. THE DERIVATION CHAIN FROM AXIOM-0

The confinement signature derives from Axiom-0 through a traced chain:

1. **Axiom-0** $\Rightarrow$ collapse is generative; structure must return to be real.
2. **Duality identity** $\Rightarrow F + \omega = 1$.
3. **Log-integrity** $\Rightarrow \kappa = \sum w_i \ln c_i$; forced by the multiplicative nature of collapse across independent channels.
4. **Integrity composite** $\Rightarrow \mathrm{IC} = \exp(\kappa)$; the unique composite respecting multiplicative structure.
5. **Integrity bound** $\Rightarrow \mathrm{IC} \leq F$. The gap $\Delta = F - \mathrm{IC}$ measures heterogeneity.
6. **Guard band** $\Rightarrow c_i \in [\varepsilon, 1-\varepsilon]$; prevents pole at $c_i = 0$.
7. **Channel death** $\Rightarrow$ binding annihilates channels, $c_i \to \varepsilon$, κ drops by $k \cdot \frac{\ln \varepsilon}{n}$, IC collapses exponentially.

Every step is forced by the axiom or by the mathematics it implies. Nothing is tuned.

XV. REPRODUCIBILITY: CASEPACK BUNDLE

All results in this paper are reproducible via a single command. The reference implementation ships a CasePack-style bundle (`casepacks/confinement_T3/`) containing:

1. **PDG raw table**: the 31 particles (17 fundamental + 14 composite) with all quantum numbers and mass/lifetime data transcribed from PDG 2024 [5] (`raw_particles.csv`).
2. **Constructed trace vectors**: the 8-channel normalized vectors for each particle, computed under the frozen contract (`expected/trace_vectors.json`).
3. **Run manifest**: contract reference, closure paths, frozen parameters, and expected outputs (`manifest.json`).
4. **Script entrypoint**: a single Python script that reads the raw table, constructs trace vectors, computes kernel invariants, verifies Theorem T3 (19/19 sub-tests), and produces a conformance receipt (`run_confinement_T3.py`).

One-Command Rerun

```
$ cd casepacks/confinement_T3
$ python run_confinement_T3.py
```

Produces: kernel invariants for all 31 particles, Theorem T3 verdict (19/19 sub-tests), guard band robustness table, and exotic hadron verification. All frozen parameters are sourced from the contract, not hardcoded in the script.

The CasePack references `SM.INTSTACK.v1.yaml` (Sec. IV) and the closure `closures/standard_model/subatomic_kernel.py`. The full repository is at https://github.com/calebpruett927/GENERATIVE-COLLAPSE-DYNAMICS.

XVI. CONCLUSIONS

We have shown that quark confinement produces a sharp, quantitative structural signature in the GCD kernel: a 98.1% collapse in the integrity composite at the quark→hadron boundary (Theorem T3, 19/19 sub-tests).

The mechanism is *channel death*: binding annihilates specific observable channels, and the geometric mean translates this into a two-order-of-magnitude integrity cliff. The arithmetic mean drops by only 28.5%, confirming the catastrophic collapse is specific to IC.

Three lines of evidence establish robustness:

1. **Guard band invariance**: the 14/14 bound holds across $\varepsilon \in [10^{-12}, 10^{-2}]$, nine orders of magnitude (Table VII).

2. **Channel basis necessity**: the 8-channel basis is forced by PDG's classification of measurable quantum numbers (Sec. IX).

3. **Exotic hadron confirmation**: 6 LHCb-confirmed pentaquarks and tetraquarks fall in the hadron IC band, extending the bound to 20/20 composite particles (Table VIII).

This result occupies a distinct space from the QCD approach: QCD asks *why* quarks are confined (dynamics, gauge theory); the kernel asks *what* confinement does to observable structure (channel death, IC cliff, gap amplification).

The kernel does not solve the Millennium Problem. It provides something complementary: a measurable, falsifiable, computable signature that characterizes confinement's structural consequences without requiring a non-perturbative proof. The signature derives from a single axiom through a traced chain, applies to any domain where binding annihilates channels, and generates predictions for glueballs and the quark-gluon plasma phase transition.

Acknowledgments. C.P. thanks C.Pau. for the axiom, the frozen-contract discipline, and the framework that makes this analysis possible. All particle data from PDG 2024 [5]. Reference implementation: `https://github.com/calebpruett927/GENERATIVE-COLLAPSE-DYNAMICS`.

SS1m Proof-Battery Receipt — SS1m-CONFINE-T3-2025

Status:	CLOSED	**Revision**:	2025-07-11
Sections:	16	**Equations**:	18
Tables:	10	**Theorems**:	1
Claims:	6	**Predictions**:	5
Sub-tests:	19	**References**:	12
Domains:	1	**Pages**:	8

Verdict: Theorem T3 proven 19/19. Guard band invariant across $\varepsilon \in [10^{-12}, 10^{-2}]$. Exotic hadrons extend bound to 20/20. Proof battery closed.

Note: "proof battery closed" = all theorem sub-tests pass. This is a single-edition verification, not a PRE→POST canon weld (which requires two declared editions under a frozen contract).
